Exploring the link between alcohol use and mental health in India.

Abstract

This study uses national data to explore how alcohol consumption patterns in India relate to stress, depression, and suicide, highlighting key risk groups and supporting the need for stronger public health action

Datasets Used

1. NFHS-5 State-Level Indicators (2018–21)
2. Health Department Report Data
3. Suicide-by-Cause Dataset (2018–2023)
4. Stress Rate Dataset (2014–2023)
5. Smoking and Lifestyle Dataset

Data processing

Data was extracted from public datasets, cleaned by removing duplicates and standardizing values, grouped into categories like age brackets, and modeled in Power BI with state–year relationships and DAX measures to generate accurate insights.

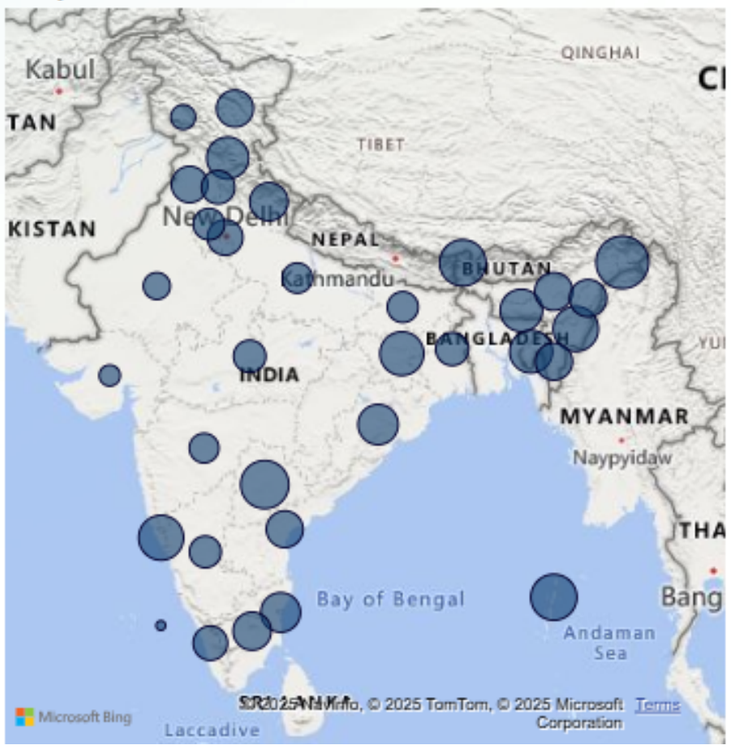
Objective

- Analyze state-wise and age-wise alcohol consumption trends.
- Identify links between alcohol use, stress, depression, and suicide.
- Provide data-driven insights using Power BI visualizations.

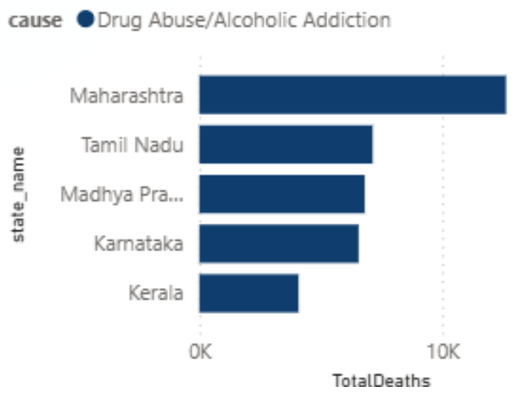
Result:

- High alcohol consumption states also show higher stress and depression levels.
- Age groups 25–34 and 35–44 have the highest drinking rates.
- Alcohol-related suicide deaths are significantly higher among males.
- Northeastern and southern states show the highest alcohol consumption.

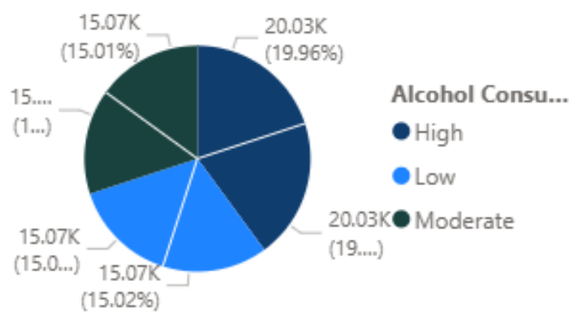
Sum of Men ALcohol % and Sum of Women Alcohol % by States and UTS



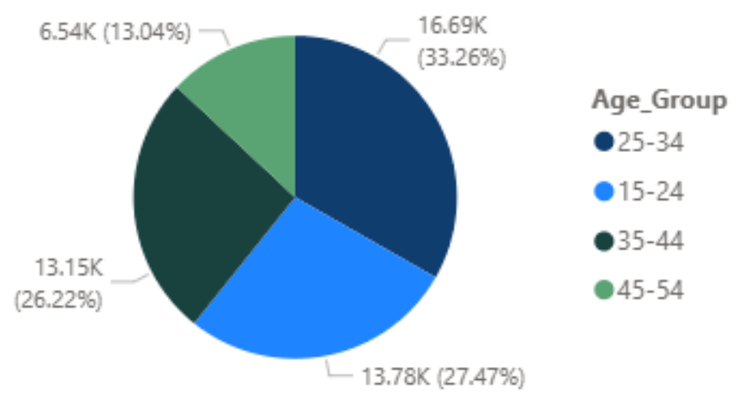
TotalDeaths by state_name and cause

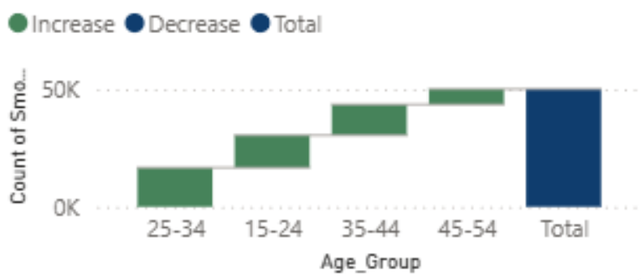


Count of Depression and Count of History of Mental Illness by Alcohol Consumption



Count of Alcohol Consumption by Age_Group





Count of Smoking Status by Age_Group
